A Introduction to Matrix Algebra and the Multivariate Normal Distribution

PSYC 943: Fundamentals of Multivariate Modeling

Lecture 5: September 25, 2013

Today's Class

- An introduction to matrix algebra
  - Scalars, vectors, and matrices
  - Basic matrix operations
  - Advanced matrix operations

- An introduction to SAS PROC IML
  - Interactive matrix language

Why Learning a Little Matrix Algebra is Important

- Matrix algebra is the alphabet of the language of statistics
  - You will most likely encounter formulae with matrices very quickly

- For example, imagine you were interested in analyzing some repeated measures data…but things don't go as planned
  - From the SAS User's Guide (PROC MIXED):

Formulation of the Mixed Model

The previous general linear model is certainly a useful one (Sea
although you still assume normality.

The mixed model is written as

$$\mathbf{y} = \mathbf{X}\boldsymbol{\beta} + \mathbf{Z}\boldsymbol{\gamma} + \boldsymbol{\varepsilon}$$

where everything is the same as in the general linear model ex
Henderson (1990) and Searle, Casella, and McCulloch (1992) f

A key assumption in the foregoing analysis is that $\boldsymbol{\gamma}$ and $\boldsymbol{\varepsilon}$ are

$$\mathrm{E}\begin{bmatrix} \boldsymbol{\gamma} \\ \boldsymbol{\varepsilon} \end{bmatrix} = \begin{bmatrix} \mathbf{0} \\ \mathbf{0} \end{bmatrix}$$

$$\mathrm{Var}\begin{bmatrix} \boldsymbol{\gamma} \\ \boldsymbol{\varepsilon} \end{bmatrix} = \begin{bmatrix} \mathbf{G} & \mathbf{0} \\ \mathbf{0} & \mathbf{R} \end{bmatrix}$$

The variance of $\mathbf{y}$ is, therefore, $\mathbf{V} = \mathbf{Z}\mathbf{G}\mathbf{Z}' + \mathbf{R}$. You can mode

Estimating Covariance Parameters in the Mixed Model

Estimation is more difficult in the mixed model than in the general linear model. Not only do y

$$(\mathbf{y} - \mathbf{X}\boldsymbol{\beta})'\mathbf{V}^{-1}(\mathbf{y} - \mathbf{X}\boldsymbol{\beta})$$

However, it requires knowledge of $\mathbf{V}$ and, therefore, knowledge of $\mathbf{G}$ and $\mathbf{R}$. Lacking such infc

In many situations, the best approach is to use *likelihood-based* methods, exploiting the ass
(REML). A favorable theoretical property of ML and REML is that they accommodate data tha

PROC MIXED constructs an objective function associated with ML or REML and maximizes i

$$\text{ML}: \quad l(\mathbf{G},\mathbf{R}) = -\frac{1}{2}\log|\mathbf{V}| - \frac{1}{2}\mathbf{r}'\mathbf{V}^{-1}\mathbf{r} - \frac{n}{2}\log(2\pi)$$

$$\text{REML}: \quad l_R(\mathbf{G},\mathbf{R}) = -\frac{1}{2}\log|\mathbf{V}| - \frac{1}{2}\log|\mathbf{X}'\mathbf{V}^{-1}\mathbf{X}| - \frac{1}{2}\mathbf{r}'\mathbf{V}^{-1}\mathbf{r} - \frac{n-p}{2}\log(2\pi)\}$$

where $\mathbf{r} = \mathbf{y} - \mathbf{X}(\mathbf{X}'\mathbf{V}^{-1}\mathbf{X})^{-}\mathbf{X}'\mathbf{V}^{-1}\mathbf{y}$ and p is the rank of $\mathbf{X}$. PROC MIXED actually minimiz
analytical details for implementing a QR-decomposition approach to the problem. Wolfinger, T

Introduction and Motivation

- Nearly all multivariate statistical techniques are described with matrix algebra

- When new methods are developed, the first published work typically involves matrices
  - It makes technical writing more concise – formulae are smaller

- Have you seen:
  - $(\boldsymbol{X}^T\boldsymbol{X})^{-1}\boldsymbol{X}^T\boldsymbol{y}$
  - $\boldsymbol{\Lambda\Phi\Lambda}^T + \boldsymbol{\Psi}$

- **Useful tip:** matrix algebra is a great way to get out of conversations and other awkward moments

Definitions

- We begin this class with some general definitions (from dictionary.com):
  - **Matrix:**
  1. A rectangular array of numeric or algebraic quantities subject to mathematical operations
  2. The substrate on or within which a fungus grows

  - **Algebra:**
  1. A branch of mathematics in which symbols, usually **letters** of the alphabet, represent numbers or members of a specified set and are used to represent quantities and to express general relationships that hold for all members of the set

  2. A set together with a pair of **binary operations** defined on the set. Usually, the set and the operations include an **identity element**, and the operations are **commutative** or **associative**

Why Learn Matrix Algebra

- Matrix algebra can seem very abstract from the purposes of this class (and statistics in general)

- Learning matrix algebra is important for:
  - Understanding how statistical methods work
    - And when to use them (or not use them)
  - Understanding what statistical methods mean
  - Reading and writing results from new statistical methods

- Today's class is the first lecture of learning the language of multivariate statistics

DATA EXAMPLE AND SAS

A Guiding Example

- To demonstrate matrix algebra, we will make use of data
- Imagine that somehow I collected data SAT test scores for both the Math (SATM) and Verbal (SATV) sections of 1,000 students

- The descriptive statistics of this data set are given below:

Statistic	SATV	SATM
Mean	499.3	498.3
SD	49.8	81.2

Correlation

SATV	1.00	0.78
SATM	0.78	1.00

The Data…

In Excel:

	A	B	C	D	E	F	G
1	SATV	SATM					
2	520	580					
3	520	550					
4	460	440					
5	560	530					
6	430	440					
7	490	530					
8	570	580					
9	530	570					
10	490	540

Matrix Computing: PROC IML

- To help demonstrate the topics we will discuss today, I will be showing examples in SAS PROC IML

- The Interactive Matrix Language (IML) is a scientific computing package in SAS that typically used for statistical routines that aren't programed elsewhere in SAS

- Useful documentation for IML:

http://support.sas.com/documentation/cdl/en/imlug/64248/HTML/default/viewer.htm#langref_toc.htm

- A great web reference for IML:

http://www.psych.yorku.ca/lab/sas/iml.htm

PROC IML Basics

- Proc IML is a proc step in SAS that runs without needing to use a preliminary data step

- To use IML the following lines of syntax are placed in a SAS file:

```
PROC IML;
RESET PRINT;

*IML SYNTAX GOES IN HERE;

QUIT;
```

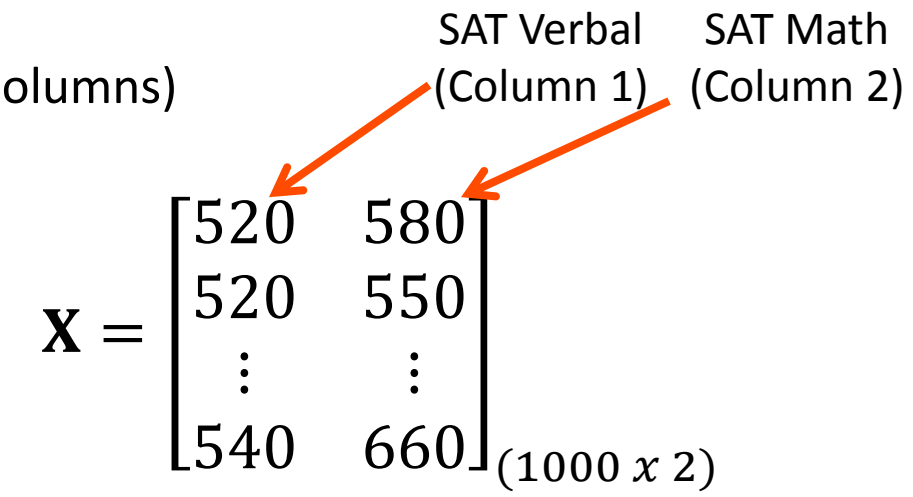
- The “reset print;” line makes every result get printed in the output window

- The IML syntax will go between the “reset print;” and the “quit;”

DEFINITIONS OF MATRICES, VECTORS, AND SCALARS

Matrices

- A matrix is a rectangular array of data
  - Used for storing numbers
- Matrices can have unlimited dimensions
  - For our purposes all matrices will have two dimensions:
    - Row
    - Columns
- Matrices are symbolized by **boldface** font in text, typically with capital letters
  - Size (r rows x c columns)



Vectors

- A vector is a matrix where one dimension is equal to size 1
  - Column vector: a matrix of size $r \; x \; 1$

$$\boldsymbol{x}_{\cdot 1} = \begin{bmatrix} 520 \\ 520 \\ \vdots \\ 540 \end{bmatrix}_{1000 \; x \; 1}$$

  - Row vector: a matrix of size $1 \; x \; c$

$$\boldsymbol{x}_{1\cdot} = [520 \quad 580]_{1 \; x \; 2}$$

- Vectors are typically written in **boldface** font text, usually with lowercase letters

- The dots in the subscripts $\boldsymbol{x}_{\cdot 1}$ and $\boldsymbol{x}_{1\cdot}$ represent the dimension aggregated across in the vector
  - $\boldsymbol{x}_{1\cdot}$ is the first row and **all** columns of $\mathbf{X}$
  - $\boldsymbol{x}_{\cdot 1}$ is the first column and **all** rows of $\mathbf{X}$
  - Sometimes the rows and columns are separated by a comma (making it possible to read double-digits in either dimension)

Matrix Elements

- A matrix (or vector) is composed of a set of elements
  - Each element is denoted by its position in the matrix (row and column)

- For our matrix of data $\mathbf{X}$ (size 1000 rows and 2 columns), each element is denoted by:

$$x_{ij}$$

  - The first subscript is the index for the rows: i = 1,…,r (= 1000)
  - The second subscript is the index for the columns: j = 1,…,c (= 2)

$$\mathbf{X} = \begin{bmatrix} x_{11} & x_{12} \\ x_{21} & x_{22} \\ \vdots & \vdots \\ x_{1000,1} & x_{1000,2} \end{bmatrix}_{(1000\ x\ 2)}$$

Scalars

- A scalar is just a single number
- The name scalar is important: the number "scales" a vector – it can make a vector "longer" or "shorter"
- Scalars are typically written without boldface:

$$x_{11} = 520$$

- Each element of a matrix is a scalar

Matrix Transpose

- The transpose of a matrix is a reorganization of the matrix by switching the indices for the rows and columns

$$\mathbf{X} = \begin{bmatrix} 520 & 580 \\ 520 & 550 \\ \vdots & \vdots \\ 540 & 660 \end{bmatrix}_{(1000\ x\ 2)}$$

$$\mathbf{X}^T = \begin{bmatrix} 520 & 520 & \cdots & 540 \\ 580 & 550 & \cdots & 660 \end{bmatrix}_{(2\ x\ 1000)}$$

- An element x_{ij} in the original matrix $\mathbf{X}$ is now x_{ji} in the transposed matrix $\mathbf{X}^T$

- **Transposes are used to align matrices for operations where the sizes of matrices matter (such as matrix multiplication)**

Types of Matrices

- **Square Matrix:** A square matrix has the same number of rows and columns
  - Correlation/covariance matrices are square matrices

- **Diagonal Matrix:** A diagonal matrix is a square matrix with non-zero diagonal elements ($x_{ij} \neq 0 \text{ for } i = j$) and zeros on the off-diagonal elements ($x_{ij} = 0 \text{ for } i \neq j$):

$$\mathbf{A} = \begin{bmatrix} 2.759 & 0 & 0 \\ 0 & 1.643 & 0 \\ 0 & 0 & 0.879 \end{bmatrix}$$

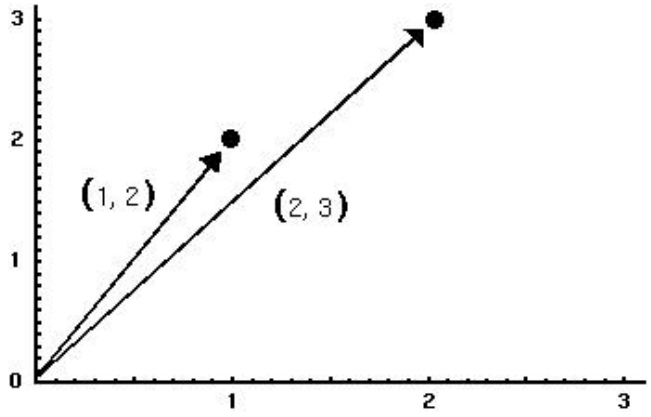
  - We will use diagonal matrices to form correlation matrices

- **Symmetric Matrix:** A symmetric matrix is a square matrix where all elements are reflected across the diagonal ($a_{ij} = a_{ji}$)
  - Correlation and covariance matrices are symmetric matrices

VECTORS

Vectors in Space…

- Vectors (row or column) can be represented as lines on a Cartesian coordinate system (a graph)
- Consider the vectors: $\mathbf{a} = \begin{bmatrix} 1 \\ 2 \end{bmatrix}$ and $\mathbf{b} = \begin{bmatrix} 2 \\ 3 \end{bmatrix}$
- A graph of these vectors would be:



- **Question:** how would a column vector for each of our example variables (SATM and SATV) be plotted?

Vector Length

- The length of a vector emanating from the origin is given by the Pythagorean formula
  - This is also called the Euclidean distance between the endpoint of the vector and the origin

$$L_{\mathbf{x}} = \sqrt{x_{11}^2 + x_{21}^2 + \cdots + x_{r1}^2} = \|\mathbf{x}\|$$

- From the last slide: $\|\mathbf{a}\| = \sqrt{5} = 2.24$; $\|\mathbf{b}\| = \sqrt{13} = 3.61$

- From our data:

$$\|\mathbf{SATV}\| = 15{,}868.138; \|\mathbf{SATM}\| = 15{,}964.42$$

- **In data:** length is an analog to the standard deviation
  - In mean-centered variables, the length is the square root of the sum of mean deviations (not quite the SD, but close)

Vector Addition

- Vectors can be added together so that a new vector is formed

- Vector addition is done element-wise, by adding each of the respective elements together:
  - The new vector has the same number of rows and columns

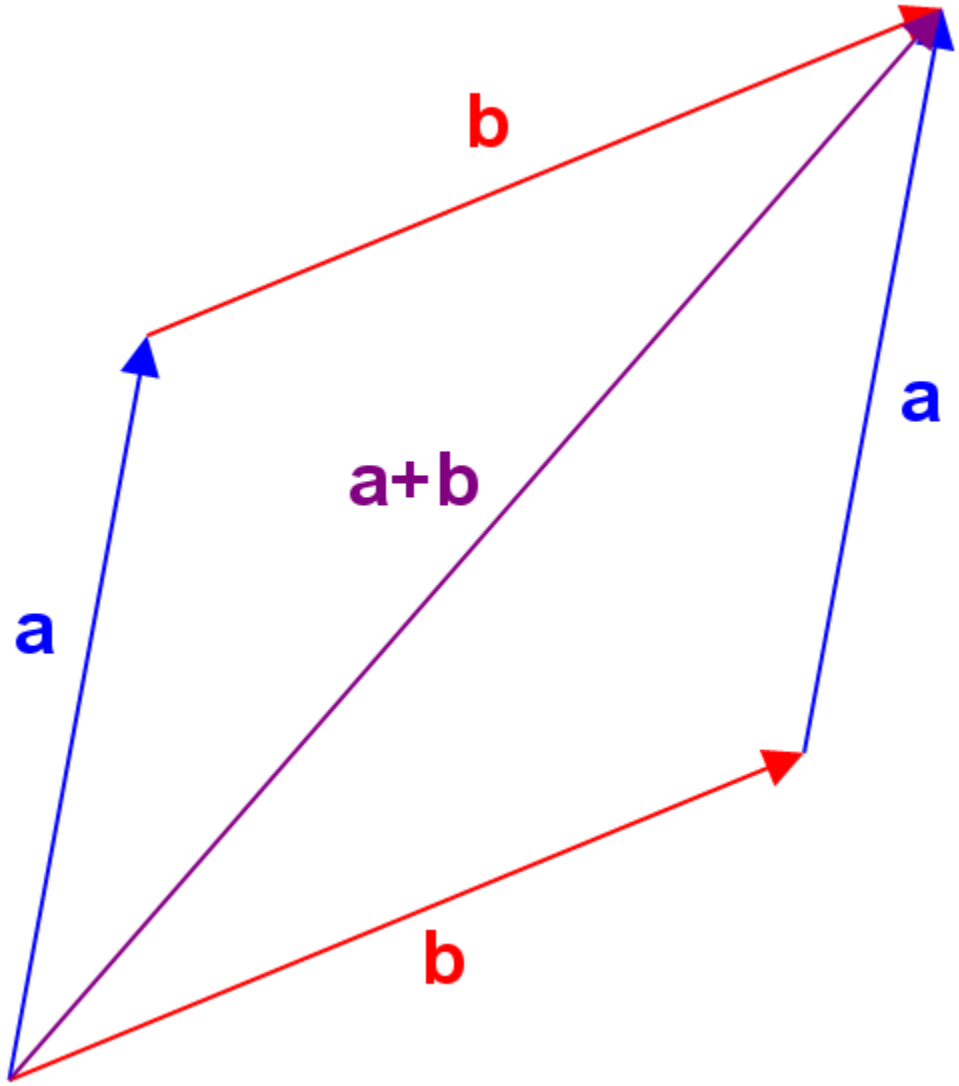
$$\mathbf{c} = \mathbf{a} + \mathbf{b} = \begin{bmatrix} 1 \\ 2 \end{bmatrix} + \begin{bmatrix} 2 \\ 3 \end{bmatrix} = \begin{bmatrix} 3 \\ 5 \end{bmatrix}$$

  - Geometrically, this creates a new vector along either of the previous two
    - Starting at the origin and ending at a new point in space

- **In Data:** a new variable (say, SAT total) is the result of vector addition

$$\boldsymbol{SAT_{TOTAL}} = \boldsymbol{x}_{.1} + \boldsymbol{x}_{.2}$$

Vector Addition: Geometrically



Vector Multiplication by Scalar

- Vectors can be multiplied by scalars
  - All elements are multiplied by the scalar

$$\mathbf{d} = 2\mathbf{a} = 2\begin{bmatrix}1\\2\end{bmatrix} = \begin{bmatrix}2\\4\end{bmatrix}$$

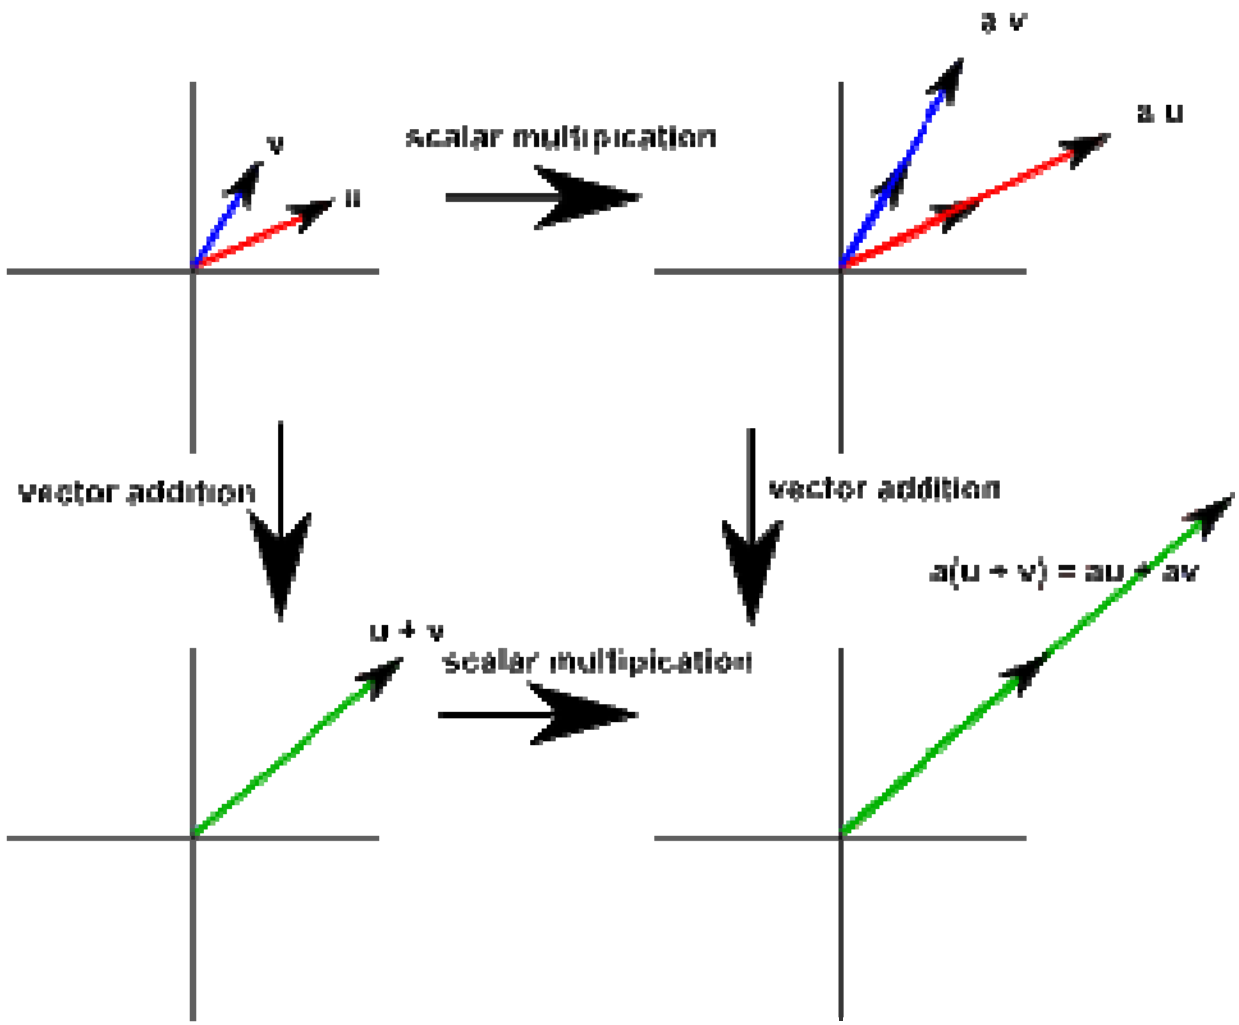
- Scalar multiplication changes the length of the vector:

$$\|\mathbf{d}\| = \sqrt{2^2 + 4^2} = \sqrt{20} = 4.47$$

- This is where the term scalar comes from: a scalar ends up "rescaling" (resizing) a vector

- **In Data:** the GLM (where **X** is a matrix of data) the fixed effects (slopes) are scalars multiplying the data

Scalar Multiplication: Geometrically



Linear Combinations

- Addition of a set of vectors (all multiplied by scalars) is called a linear combination:

$$\mathbf{y} = a_1\mathbf{x}_1 + a_2\mathbf{x}_2 + \cdots + a_k\mathbf{x}_k$$

- Here, $\mathbf{y}$ is the linear combination
  - For all *k* vectors, the set of all possible linear combinations is called their span
  - Typically not thought of in most analyses – but when working with things that don't exist (latent variables) becomes somewhat important

- **In Data**: linear combinations happen frequently:
  - Linear models (i.e., Regression and ANOVA)
  - Principal components analysis (later today)

Linear Dependencies

- A set of vectors are said to be linearly dependent if

$$a_1\mathbf{x}_1 + a_2\mathbf{x}_2 + \cdots + a_k\mathbf{x}_k = 0$$

-and-

$a_1, a_2, \ldots, a_k$ are all **not** zero

- Example: let's make a new variable – SAT Total:

$$\mathbf{SAT_{total}} = 1 * \mathbf{SATV} + 1 * \mathbf{SATM}$$

- The new variable is linearly dependent with the others:

$$(1) * \mathbf{SATV} + (1) * \mathbf{SATM} + (-1) * \mathbf{SAT_{total}} = \mathbf{0}$$

- **In Data**: (multi) collinearity is a linear dependency. Linear dependencies are bad for statistical analyses that use matrix inverses (discussed soon).

Inner (Dot) Product of Vectors

- An important concept in vector geometry is that of the inner product of two vectors
  - The inner product is also called the dot product

$$\mathbf{a} \cdot \mathbf{b} = \mathbf{a}^T \mathbf{b} = a_{11} b_{11} + a_{21} b_{21} + \cdots + a_{N1} b_{N1} = \sum_{i=1}^{N} a_{i1} b_{i1}$$

- The dot or inner product is related to the angle between vectors and to the projection of one vector onto another

- From our example: $\mathbf{a} \cdot \mathbf{b} = 1 * 2 + 2 * 3 = 8$
- From our data: $\boldsymbol{x}_{.1} \cdot \boldsymbol{x}_{.2} = 251{,}928{,}400$

- **<u>In data:</u>** the angle between vectors is related to the correlation between variables and the projection is related to regression/ANOVA/linear models

Angle Between Vectors

- As vectors are conceptualized geometrically, the angle between two vectors can be calculated

$$\theta_{ab} = \cos^{-1}\left(\frac{\mathbf{a} \cdot \boldsymbol{b}}{\|\mathbf{a}\|\|\mathbf{b}\|}\right)$$

- From the example:

$$\theta_{ab} = \cos^{-1}\left(\frac{8}{\sqrt{5}\sqrt{13}}\right) = 0.12$$

- From our data:

$$\theta_{SATV,SATM} = \cos^{-1}\left(\frac{251{,}928{,}400}{\sqrt{15{,}868.138}\sqrt{15{,}946.42}}\right) = 0.105$$

In Data: Cosine Angle = Correlation

- If you have data that are:
  - Placed into vectors
  - Centered by the mean (subtract the mean from each observation)

- …then the cosine of the angle between those vectors is the correlation between the variables:

$$r_{ab} = cos(\theta_{ab}) = \frac{\mathbf{a} \cdot \boldsymbol{b}}{\|\mathbf{a}\|\|\mathbf{b}\|} = \frac{\sum_{i=1}^{N}(a_{i1} - \bar{a})(b_{i1} - \bar{b})}{\sqrt{\sum_{i=1}^{N}(a_{i1} - \bar{a})^2}\sqrt{\sum_{i=1}^{N}(b_{i1} - \bar{b})^2}}$$

For the SAT example data (using mean centered variables):

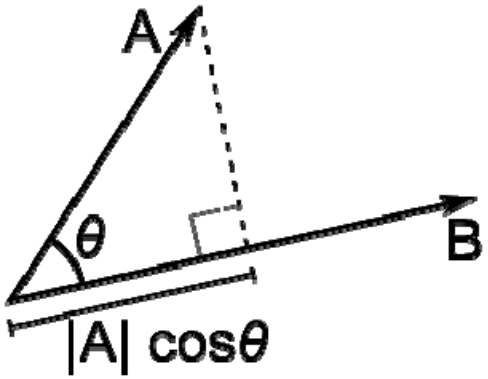
$$r_{SATV,SATM} = \cos(\theta_{SATVc,SATMc}) = \cos\left(\frac{3{,}132{,}223.6}{1{,}573.956 * 2{,}567.0425}\right)$$

$$= .775$$

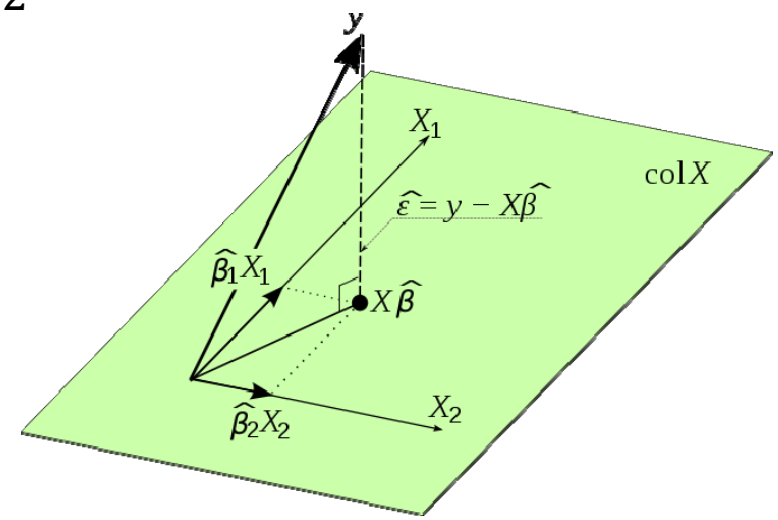
Vector Projections

- A final vector property that shows up in statistical terms frequently is that of a projection

- The **projection** of a vector $\mathbf{a}$ onto $\mathbf{b}$ is the orthogonal projection of $\mathbf{a}$ onto the straight line defined by $\mathbf{b}$
  - The projection is the "shadow" of one vector onto the other:



$$\mathbf{a}_{\text{proj }\mathbf{b}} = \frac{\mathbf{a} \cdot \mathbf{b}}{\|\mathbf{b}\|^2}\mathbf{b}$$



- **In data:** linear models can be thought of as projections

Vector Projections Example

- To provide a bit more context for vector projections, let's consider the projection of SATV onto SATM:

$$\boldsymbol{SATV}_{\text{proj }\boldsymbol{SATM}} = \frac{\boldsymbol{SATV} \cdot \boldsymbol{SATM}}{\|\boldsymbol{SATM}\|^2}\boldsymbol{SATM}$$

- The first portion turns out to be:

$$\frac{\boldsymbol{SATV} \cdot \boldsymbol{SATM}}{\|\boldsymbol{SATM}\|^2} = \frac{251{,}928{,}400}{\|15{,}964.42\|^2} = .475$$

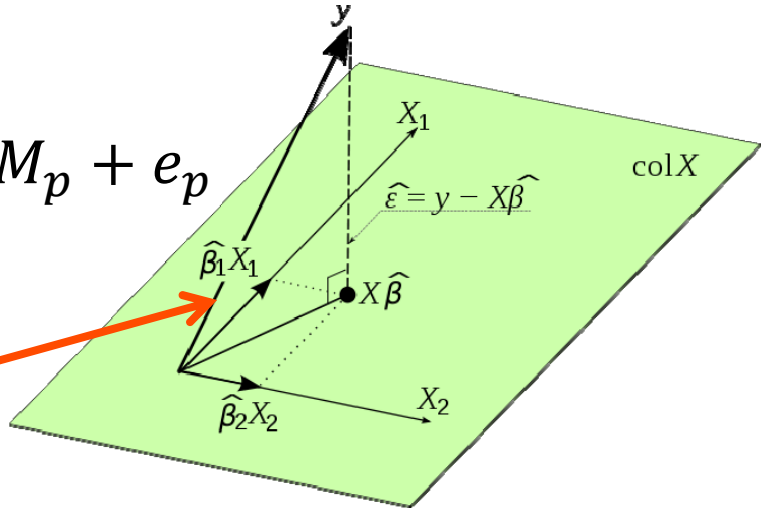
- This is also the regression slope β_1:

$$SATV_p = \beta_0 + \beta_1 SATM_p + e_p$$

The GLM Procedure

Dependent Variable: satv

Parameter	Estimate
Intercept	262.4819995
satm	0.4753206



MATRIX ALGEBRA

Moving from Vectors to Matrices

- A matrix can be thought of as a collection of vectors
  - Matrix operations are vector operations on steroids
- Matrix algebra defines a set of operations and entities on matrices
  - I will present a version meant to mirror your previous algebra experiences
- Definitions:
  - Identity matrix
  - Zero vector
  - Ones vector
- Basic Operations:
  - Addition
  - Subtraction
  - Multiplication
  - “Division”

Matrix Addition and Subtraction

- Matrix addition and subtraction are much like vector addition/subtraction

- Rules:
  - Matrices must be the same size (rows and columns)

- Method:
  - The new matrix is constructed of element-by-element addition/subtraction of the previous matrices

- Order:
  - The order of the matrices (pre- and post-) does not matter

Matrix Addition/Subtraction

$$\mathbf{A} = \begin{bmatrix} a_{11} & a_{12} \\ a_{21} & a_{22} \\ a_{31} & a_{32} \\ a_{41} & a_{42} \end{bmatrix} \qquad \mathbf{B} = \begin{bmatrix} b_{11} & b_{12} \\ b_{21} & b_{22} \\ b_{31} & b_{32} \\ b_{41} & b_{42} \end{bmatrix}$$

$$\mathbf{A} + \mathbf{B} = \begin{bmatrix} a_{11} + b_{11} & a_{12} + b_{12} \\ a_{21} + b_{21} & a_{22} + b_{22} \\ a_{31} + b_{31} & a_{32} + b_{32} \\ a_{41} + b_{41} & a_{42} + b_{42} \end{bmatrix} \qquad \mathbf{A} - \mathbf{B} = \begin{bmatrix} a_{11} - b_{11} & a_{12} - b_{12} \\ a_{21} - b_{21} & a_{22} - b_{22} \\ a_{31} - b_{31} & a_{32} - b_{32} \\ a_{41} - b_{41} & a_{42} - b_{42} \end{bmatrix}$$

Matrix Multiplication

- Matrix multiplication is a bit more complicated
  - The new matrix may be a different size from either of the two multiplying matrices

$$\mathbf{A}_{(r\ x\ c)}\mathbf{B}_{(c\ x\ k)} = \mathbf{C}_{(r\ x\ k)}$$

- Rules:
  - Pre-multiplying matrix must have number of columns equal to the number of rows of the post-multiplying matrix

- Method:
  - The elements of the new matrix consist of the inner (dot) product of the row vectors of the pre-multiplying matrix and the column vectors of the post-multiplying matrix

- Order:
  - The order of the matrices (pre- and post-) matters

Matrix Multiplication

$$\mathbf{A} = \begin{bmatrix} a_{11} & a_{12} \\ a_{21} & a_{22} \\ a_{31} & a_{32} \\ a_{41} & a_{42} \end{bmatrix} \quad \mathbf{B} = \begin{bmatrix} b_{11} & b_{12} & b_{13} \\ b_{21} & b_{22} & b_{23} \end{bmatrix}$$

$$\mathbf{AB} = \begin{bmatrix} a_{11}b_{11} + a_{12}b_{21} & a_{11}b_{12} + a_{12}b_{22} & a_{11}b_{13} + a_{12}b_{23} \\ a_{21}b_{11} + a_{22}b_{21} & a_{21}b_{12} + a_{22}b_{22} & a_{21}b_{13} + a_{22}b_{23} \\ a_{31}b_{11} + a_{32}b_{21} & a_{31}b_{12} + a_{32}b_{22} & a_{31}b_{13} + a_{32}b_{23} \\ a_{41}b_{11} + a_{42}b_{21} & a_{41}b_{12} + a_{42}b_{22} & a_{41}b_{13} + a_{42}b_{23} \end{bmatrix}$$

Multiplication in Statistics

- Many statistical formulae with summation can be re-expressed with matrices

- A common matrix multiplication form is: $\mathbf{X}^T\mathbf{X}$
  - Diagonal elements: $\sum_{i=1}^{N} X_i^2$
  - Off-diagonal elements: $\sum_{i=1}^{N} X_{ia}X_{ib}$

- For our SAT example:

$$\mathbf{X}^T\mathbf{X} = \begin{bmatrix} \sum_{i=1}^{N} SATV_i^2 & \sum_{i=1}^{N} SATV_i SATM_i \\ \sum_{i=1}^{N} SATV_i SATM_i & \sum_{i=1}^{N} SATM_i^2 \end{bmatrix}$$

$$= \begin{bmatrix} 251{,}797{,}800 & 251{,}928{,}400 \\ 251{,}928{,}400 & 254{,}862{,}700 \end{bmatrix}$$

Identity Matrix

- The identity matrix is a matrix that, when pre- or post- multiplied by another matrix results in the original matrix:

$$\mathbf{AI} = \mathbf{A}$$
$$\mathbf{IA} = \mathbf{A}$$

- The identity matrix is a square matrix that has:
  - Diagonal elements = 1
  - Off-diagonal elements = 0

$$I_{(3\ x\ 3)} = \begin{bmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{bmatrix}$$

Zero Vector

- The zero vector is a column vector of zeros

$$\mathbf{0}_{(3\ x\ 1)} = \begin{bmatrix} 0 \\ 0 \\ 0 \end{bmatrix}$$

- When pre- or post- multiplied the result is the zero vector:

$$\mathbf{A0} = \mathbf{0}$$
$$\mathbf{0A} = \mathbf{0}$$

Ones Vector

- A ones vector is a column vector of 1s:

$$\mathbf{1}_{(3\ x\ 1)} = \begin{bmatrix} 1 \\ 1 \\ 1 \end{bmatrix}$$

- The ones vector is useful for calculating statistical terms, such as the mean vector and the covariance matrix

Matrix "Division": The Inverse Matrix

- Division from algebra:
  - First: $\frac{a}{b} = \frac{1}{b}a = b^{-1}a$
  - Second: $\frac{a}{a} = 1$

- "Division" in matrices serves a similar role
  - For square and symmetric matrices, an inverse matrix is a matrix that when pre- or post- multiplied with another matrix produces the identity matrix:

$$\mathbf{A}^{-1}\mathbf{A} = \mathbf{I}$$
$$\mathbf{A}\mathbf{A}^{-1} = \mathbf{I}$$

- Calculation of the matrix inverse is complicated
  - Even computers have a tough time

- Not all matrices can be inverted
  - Non-invertible matrices are called singular matrices
    - In statistics, singular matrices are commonly caused by linear dependencies

The Inverse

- **In data:** the inverse shows up constantly in statistics
  - Models which assume some type of (multivariate) normality need an inverse covariance matrix

- Using our SAT example
  - Our data matrix was size (1000 x 2), which is not invertible
  - However $\mathbf{X}^T\mathbf{X}$ was size (2 x 2) – square, and symmetric

$$\mathbf{X}^T\mathbf{X} = \begin{bmatrix} 251{,}797{,}800 & 251{,}928{,}400 \\ 251{,}928{,}400 & 254{,}862{,}700 \end{bmatrix}$$

  - The inverse is:

$$(\mathbf{X}^T\mathbf{X})^{-1} = \begin{bmatrix} 3.61E-7 & -3.57E-7 \\ -3.57E-7 & 3.56E-7 \end{bmatrix}$$

Matrix Algebra Operations

- $(\mathbf{A}+\mathbf{B})+\mathbf{C}=$
  $\mathbf{A}+(\mathbf{B}+\mathbf{C})$
- $\mathbf{A}+\mathbf{B}=\mathbf{B}+\mathbf{A}$
- $c(\mathbf{A}+\mathbf{B})=c\mathbf{A}+c\mathbf{B}$
- $(c+d)\mathbf{A}=c\mathbf{A}+d\mathbf{A}$
- $(\mathbf{A}+\mathbf{B})^T=\mathbf{A}^T+\mathbf{B}^T$
- $(cd)\mathbf{A}=c(d\mathbf{A})$
- $(c\mathbf{A})^T=c\mathbf{A}^T$
- $c(\mathbf{AB})=(c\mathbf{A})\mathbf{B}$
- $\mathbf{A}(\mathbf{BC})=(\mathbf{AB})\mathbf{C}$
- $\mathbf{A}(\mathbf{B}+\mathbf{C})=\mathbf{AB}+\mathbf{AC}$
- $(\mathbf{AB})^T=\mathbf{B}^T\mathbf{A}^T$
- For x_j such that Ax_j exists:

$$\sum_{j=1}^{N}\mathbf{A}\mathbf{x}_j=\mathbf{A}\sum_{j=1}^{N}\mathbf{x}_j$$

$$\sum_{j=1}^{N}(\mathbf{A}\mathbf{x}_j)(\mathbf{A}\mathbf{x}_j)^T=$$

$$\mathbf{A}\left(\sum_{j=1}^{N}\mathbf{x}_j\mathbf{x}_j^T\right)\mathbf{A}^T$$

ADVANCED MATRIX OPERATIONS

Advanced Matrix Functions/Operations

- We end our matrix discussion with some advanced topics
  - All related to multivariate statistical analysis

- To help us throughout, let's consider the correlation matrix of our SAT data:

$$\mathbf{R} = \begin{bmatrix} 1.00 & 0.78 \\ 0.78 & 1.00 \end{bmatrix}$$

Matrix Trace

- For a square matrix $\mathbf{A}$ with *p* rows/columns, the trace is the sum of the diagonal elements:

$$tr\mathbf{A} = \sum_{i=1}^{p} a_{ii}$$

- For our data, the trace of the correlation matrix is 2
  - For all correlation matrices, the trace is equal to the number of variables because all diagonal elements are 1

- The trace is considered the total variance in multivariate statistics
  - Used as a target to recover when applying statistical models

Matrix Determinants

- A square matrix can be characterized by a scalar value called a determinant:

$$\det \mathbf{A} = |\mathbf{A}|$$

- Calculation of the determinant is tedious
  - Our determinant was 0.3916

- The determinant is useful in statistics:
  - Shows up in multivariate statistical distributions
  - Is a measure of "generalized" variance of multiple variables

- If the determinant is positive, the matrix is called **positive definite**
  - Is invertible

- If the determinant is not positive, the matrix is called **non-positive definite**
  - Not invertible

MULTIVARIATE STATISTICS AND DISTRIBUTIONS

Multivariate Statistics

- Up to this point in this course, we have focused on the prediction (or modeling) of a single variable
  - Conditional distributions (aka, generalized linear models)

- Multivariate statistics is about exploring **joint distributions**
  - How variables relate to each other simultaneously

- Therefore, we must adapt our conditional distributions to have multiple variables, simultaneously (later, as multiple outcomes)

- We will now look at the joint distributions of two variables $f(x_1, x_2)$ or in matrix form: $f(\mathbf{X})$ (where $\mathbf{X}$ is size N x 2; $f(\mathbf{X})$ gives a scalar/single number)
  - Beginning with two, then moving to anything more than two
  - We will begin by looking at **multivariate descriptive statistics**
    - **Mean vectors and covariance matrices**

- Today, we will only consider the **joint distribution** of sets of variables – but next time we will put this into a GLM-like setup
  - The **joint distribution** will the be conditional on other variables

Multiple Means: The Mean Vector

- We can use a vector to describe the set of means for our data

$$\bar{\mathbf{x}} = \frac{1}{N}\mathbf{X}^T\mathbf{1} = \begin{bmatrix} \bar{x}_1 \\ \bar{x}_2 \\ \vdots \\ \bar{x}_V \end{bmatrix}$$

  - Here $\mathbf{1}$ is a N x 1 vector of 1s
  - The resulting mean vector is a *v* x 1 vector of means

- For our data:

$$\bar{\mathbf{x}} = \begin{bmatrix} 499.32 \\ 499.27 \end{bmatrix} = \begin{bmatrix} \bar{x}_{SATV} \\ \bar{x}_{SATM} \end{bmatrix}$$

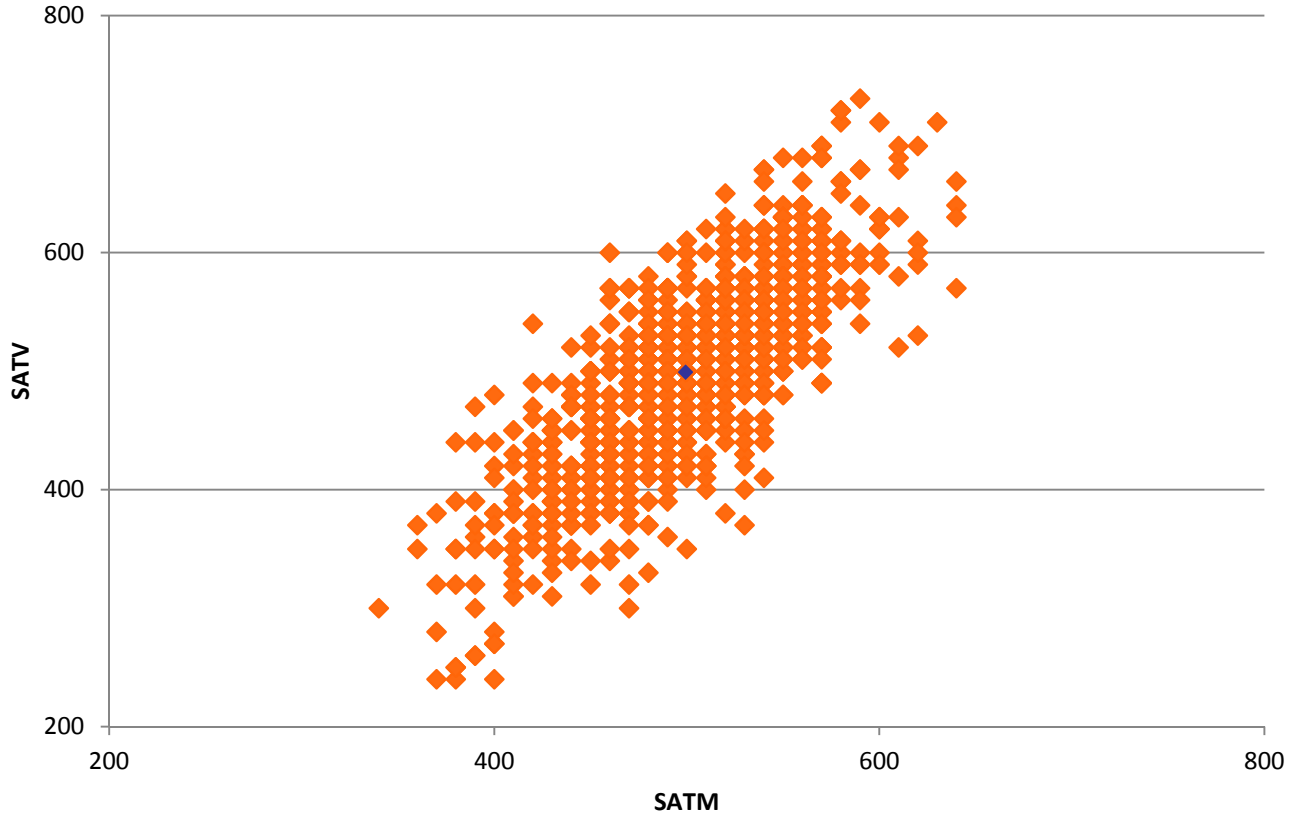
- In SAS PROC IML:

```
*ONES VECTOR WITH SAME LENGTH AS NUMBER OF OBSERVATIONS;
ONES = J(N,1,1); *J function (built in) creates a new matrix with (#rows, #cols, value of element);

*CALCULATION OF THE MEAN VECTOR;
meanvec = (1/N)*t(X)*ONES; *t() function (built in) transposes the matrix in the parentheses;
```

Mean Vector: Graphically

- The mean vector is the center of the distribution of both variables



Covariance of a Pair of Variables

- The covariance is a measure of the relatedness
  - Expressed in the product of the units of the two variables:

$$s_{x_1 x_2} = \frac{1}{N}\sum_{p=1}^{N}\left(x_{p1} - \bar{x}_1\right)\left(x_{p2} - \bar{x}_2\right)$$

  - The covariance between SATV and SATM was 3,132.22 (in SAT Verbal-Maths)
  - The denominator N is the ML version – unbiased is N-1

- Because the units of the covariance are difficult to understand, we more commonly describe association (correlation) between two variables with correlation
  - Covariance divided by the product of each variable's standard deviation

Correlation of a Pair of Varibles

- Correlation is covariance divided by the product of the standard deviation of each variable:

$$r_{x_1x_2} = \frac{s_{x_1x_2}}{\sqrt{s_{x_1}^2}\sqrt{s_{x_2}^2}}$$

  - The correlation between SATM and SATV was 0.78

- Correlation is unitless – it only ranges between -1 and 1
  - If x_1 **and** x_2 both had variances of 1, the covariance between them would be a correlation
    - Covariance of standardized variables = correlation

Covariance and Correlation in Matrices

- The covariance matrix (for any number of variables *v*) is found by:

$$\mathbf{S} = \frac{1}{N}(\mathbf{X} - \mathbf{1}\bar{\mathbf{x}}^T)^T(\mathbf{X} - \mathbf{1}\bar{\mathbf{x}}^T) = \begin{bmatrix} s_{x_1}^2 & \cdots & s_{x_1 x_V} \\ \vdots & \ddots & \vdots \\ s_{x_1 x_V} & \cdots & s_{x_V}^2 \end{bmatrix}$$

- In SAS PROC IML:

```
*ONES VECTOR WITH SAME LENGTH AS NUMBER OF OBSERVATIONS;
ONES = J(N,1,1); *J function (built in) creates a new matrix with (#rows, #cols, value of element);

*CALCULATION OF THE MEAN VECTOR;
meanvec = (1/N)*t(X)*ONES;

*CALCULATION OF THE COVARIANCE MATRIX;
mean_matrix = ONES*t(meanvec); *for covariance matrix;
cov_matrix = (1/N)*t(X - mean_matrix)*(X - mean_matrix);
```

- $\mathbf{S} = \begin{bmatrix} 2{,}477.34 & 3{,}123.22 \\ 3{,}132.22 & 6{,}589.71 \end{bmatrix}$

```
cov_matrix      2 rows      2 cols     (numeric)

2477.3376 3132.2236
3132.2236 6589.7071
```

From Covariance to Correlation

- If we take the SDs (the square root of the diagonal of the covariance matrix) and put them into a diagonal matrix $\mathbf{D}$, the correlation matrix is found by:

$$\mathbf{R} = \mathbf{D}^{-1}\mathbf{S}\mathbf{D}^{-1} = \begin{bmatrix} \frac{s_{x_1}^2}{\sqrt{s_{x_1}^2}\sqrt{s_{x_1}^2}} & \cdots & \frac{s_{x_1 x_p}}{\sqrt{s_{x_1}^2}\sqrt{s_{x_V}^2}} \\ \vdots & \ddots & \vdots \\ \frac{s_{x_1 x_V}}{\sqrt{s_{x_1}^2}\sqrt{s_{x_V}^2}} & \cdots & \frac{s_{x_V}^2}{\sqrt{s_{x_V}^2}\sqrt{s_{x_V}^2}} \end{bmatrix} = \begin{bmatrix} 1 & \cdots & r_{x_1 x_V} \\ \vdots & \ddots & \vdots \\ r_{x_1 x_V} & \cdots & 1 \end{bmatrix}$$

Example Covariance Matrix

- For our data, the covariance matrix was:

$$\mathbf{S} = \begin{bmatrix} 2{,}477.34 & 3{,}123.22 \\ 3{,}132.22 & 6{,}589.71 \end{bmatrix}$$

- The diagonal matrix $\mathbf{D}$ was:

$$\mathbf{D} = \begin{bmatrix} \sqrt{2{,}477.34} & 0 \\ 0 & \sqrt{6{,}589.71} \end{bmatrix} = \begin{bmatrix} 49.77 & 0 \\ 0 & 81.18 \end{bmatrix}$$

- The correlation matrix $\mathbf{R}$ was:

$$\mathbf{R} = \mathbf{D}^{-1}\mathbf{S}\mathbf{D}^{-1} = \begin{bmatrix} \frac{1}{49.77} & 0 \\ 0 & \frac{1}{81.18} \end{bmatrix} \begin{bmatrix} 2{,}477.34 & 3{,}123.22 \\ 3{,}132.22 & 6{,}589.71 \end{bmatrix} \begin{bmatrix} \frac{1}{49.77} & 0 \\ 0 & \frac{1}{81.18} \end{bmatrix}$$

$$\mathbf{R} = \begin{bmatrix} 1.00 & .78 \\ .78 & 1.00 \end{bmatrix}$$

In SAS:

```
*DIAGONAL MATRIX OF STANDARD DEVIATIONS FROM COVARIANCE MATRIX:;
*SQRT TAKES STANDARD DEVIATION (COVARIANCE MATRIX HAS VARIANCES);
D_matrix = SQRT(DIAG(cov_matrix));
```

D_matrix	2 rows	2 cols	(numeric)
49.77286	0		
0	81.177011		

```
*INVERSE OF D_Matrix:;
D_matrix_inv = INV(D_matrix);
```

D_matrix_inv	2 rows	2 cols	(numeric)
0.0200913	0		
0	0.0123188		

```
*CORRELATION MATRIX:;
corr_matrix = D_matrix_inv*cov_matrix*D_matrix_inv;
```

corr_matrix	2 rows	2 cols	(numeric)
1	0.7752238		
0.7752238	1		

Generalized Variance

- The determinant of the covariance matrix is the **generalized variance**

$$\text{Generalized Sample Variance} = |\mathbf{S}|$$

- It is a measure of spread across all variables
  - Reflecting how much overlap (covariance) in variables occurs in the sample
  - Amount of overlap reduces the generalized sample variance
  - Generalized variance from our SAT example: 6,514,104.5
  - Generalized variance if zero covariance/correlation: 16,324,929

```
*GENERALIZED VARIANCE:;
GEN_VAR = DET(cov_matrix);
```

```
GEN_VAR      1 row      1 col     (numeric)

6514104.5
```

- The generalized sample variance is:
  - Largest when variables are uncorrelated
  - Zero when variables form a linear dependency

- **<u>In data:</u>**
  - The generalized variance is seldom used descriptively, but shows up more frequently in maximum likelihood functions

Total Sample Variance

- The total sample variance is the sum of the variances of each variable in the sample
  - The sum of the diagonal elements of the sample covariance matrix
  - The trace of the sample covariance matrix

$$Total\ Sample\ Variance = \sum_{v=1}^{V} s_{x_i}^2 = \text{tr}\,\mathbf{S}$$

- Total sample variance for our SAT example:

```
*TOTAL SAMPLE VARIANCE;
TOT_VAR = TRACE(cov_matrix);
```

TOT_VAR 1 row 1 col (numeric)

9067.0447

- The total sample variance does not take into consideration the covariances among the variables
  - Will not equal zero if linearly dependency exists

- **<u>In data:</u>**
  - The total sample variance is commonly used as the denominator (target) when calculating variance accounted for measures

MULTIVARIATE DISTRIBUTIONS (VARIABLES ≥ 2)

Multivariate Normal Distribution

- The multivariate normal distribution is the generalization of the univariate normal distribution to multiple variables
  - The bivariate normal distribution just shown is part of the MVN

- The MVN provides the relative likelihood of observing **all** *V* variables for a subject *p* simultaneously:

$$\mathbf{x}_p = [x_{p1} \quad x_{p2} \quad \cdots \quad x_{pV}]$$

- The multivariate normal density function is:

$$f(\mathbf{x}_p) = \frac{1}{(2\pi)^{\frac{V}{2}}|\boldsymbol{\Sigma}|^{\frac{1}{2}}} \exp\left[-\frac{(\mathbf{x}_p^T - \boldsymbol{\mu})^T \boldsymbol{\Sigma}^{-1}(\mathbf{x}_p^T - \boldsymbol{\mu})}{2}\right]$$

The Multivariate Normal Distribution

$$f(\mathbf{x}_p) = \frac{1}{(2\pi)^{\frac{V}{2}}|\boldsymbol{\Sigma}|^{\frac{1}{2}}} \exp\left[-\frac{(\mathbf{x}_p^T - \boldsymbol{\mu})^T \boldsymbol{\Sigma}^{-1}(\mathbf{x}_p^T - \boldsymbol{\mu})}{2}\right]$$

- The mean vector is $\boldsymbol{\mu} = \begin{bmatrix} \mu_{x_1} \\ \mu_{x_2} \\ \vdots \\ \mu_{x_V} \end{bmatrix}$
- The covariance matrix is $\boldsymbol{\Sigma} = \begin{bmatrix} \sigma_{x_1}^2 & \sigma_{x_1x_2} & \cdots & \sigma_{x_1x_V} \\ \sigma_{x_1x_2} & \sigma_{x_2}^2 & \cdots & \sigma_{x_2x_V} \\ \vdots & \vdots & \ddots & \vdots \\ \sigma_{x_1x_V} & \sigma_{x_2x_V} & \cdots & \sigma_{x_V}^2 \end{bmatrix}$
  - The covariance matrix must be non-singular (invertible)

Comparing Univariate and Multivariate Normal Distributions

- The univariate normal distribution:

$$f(x_p) = \frac{1}{\sqrt{2\pi\sigma^2}} \exp\left[-\frac{(x-\mu)^2}{2\sigma^2}\right]$$

- The univariate normal, rewritten with a little algebra:

$$f(x_p) = \frac{1}{(2\pi)^{\frac{1}{2}}|\sigma^2|^{\frac{1}{2}}} \exp\left[-\frac{(x-\mu)\sigma^{-\frac{1}{2}}(x-\mu)}{2}\right]$$

- The multivariate normal distribution

$$f(\mathbf{x}_p) = \frac{1}{(2\pi)^{\frac{V}{2}}|\boldsymbol{\Sigma}|^{\frac{1}{2}}} \exp\left[-\frac{\left(\mathbf{x}_p^T - \boldsymbol{\mu}\right)^T \boldsymbol{\Sigma}^{-1}\left(\mathbf{x}_p^T - \boldsymbol{\mu}\right)}{2}\right]$$

  - When $V = 1$ (one variable), the MVN is a univariate normal distribution

The Exponent Term

- The term in the exponent (without the $-\frac{1}{2}$) is called the **squared Mahalanobis Distance**

$$d^2(\boldsymbol{x}_p) = (\mathbf{x}_p^T - \boldsymbol{\mu})^T \boldsymbol{\Sigma}^{-1} (\mathbf{x}_p^T - \boldsymbol{\mu})$$

  - Sometimes called the statistical distance
  - Describes how far an observation is from its mean vector, in standardized units
  - Like a multivariate Z score (but, if data are MVN, is actually distributed as a χ^2 variable with DF = number of variables in X)
  - Can be used to assess if data follow MVN

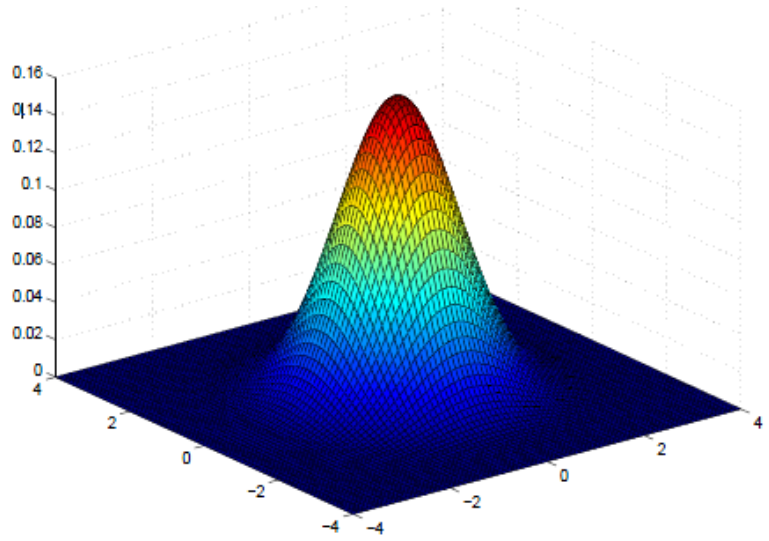
Multivariate Normal Notation

- Standard notation for the multivariate normal distribution of *v* variables is $N_v(\boldsymbol{\mu}, \boldsymbol{\Sigma})$
  - Our SAT example would use a bivariate normal: $N_2(\boldsymbol{\mu}, \boldsymbol{\Sigma})$

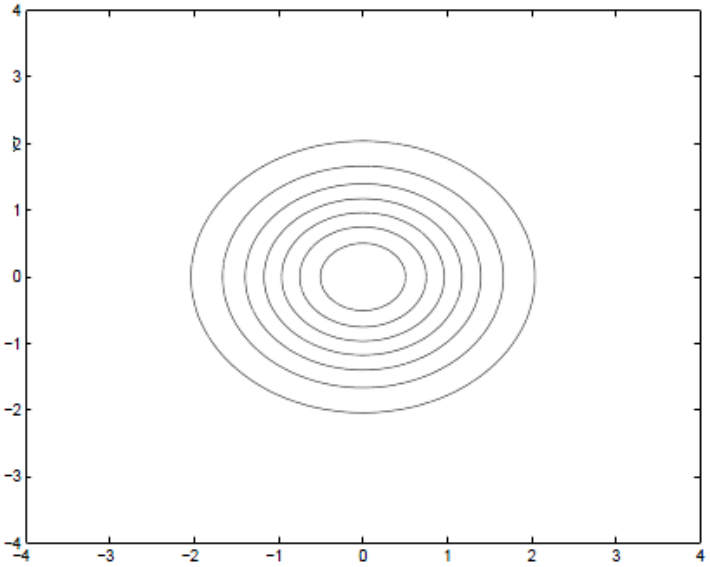
- **<u>In data:</u>**
  - The multivariate normal distribution serves as the basis for most every statistical technique commonly used in the social and educational sciences
    - General linear models (ANOVA, regression, MANOVA)
    - General linear mixed models (HLM/multilevel models)
    - Factor and structural equation models (EFA, CFA, SEM, path models)
    - Multiple imputation for missing data
  - Simply put, the world of commonly used statistics revolves around the multivariate normal distribution
    - Understanding it is the key to understanding many statistical methods

Bivariate Normal Plot #1

$$\boldsymbol{\mu} = \begin{bmatrix} \mu_{x_1} \\ \mu_{x_2} \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}, \boldsymbol{\Sigma} = \begin{bmatrix} \sigma_{x_1}^2 & \sigma_{x_1 x_2} \\ \sigma_{x_1 x_2} & \sigma_{x_2}^2 \end{bmatrix} = \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix}$$



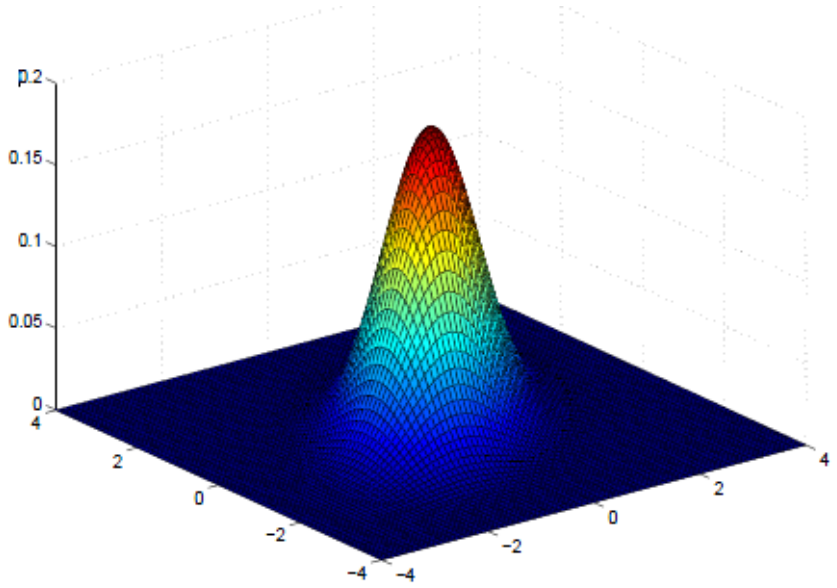
Density Surface (3D)



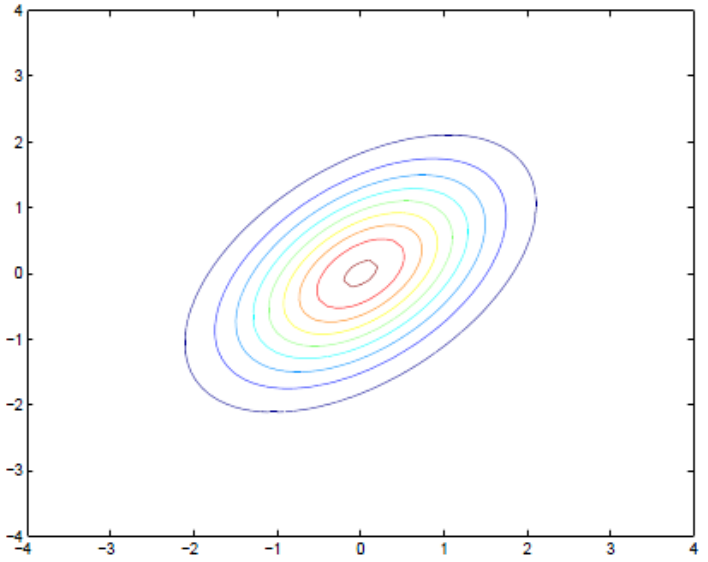
Density Surface (2D):
Contour Plot

Bivariate Normal Plot #2 (Multivariate Normal)

$$\boldsymbol{\mu} = \begin{bmatrix} \mu_{x_1} \\ \mu_{x_2} \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}, \boldsymbol{\Sigma} = \begin{bmatrix} \sigma^2_{x_1} & \sigma_{x_1 x_2} \\ \sigma_{x_1 x_2} & \sigma^2_{x_2} \end{bmatrix} = \begin{bmatrix} 1 & .5 \\ .5 & 1 \end{bmatrix}$$



Density Surface (3D)



Density Surface (2D):
Contour Plot

Multivariate Normal Properties

- The multivariate normal distribution has some useful properties that show up in statistical methods

- If $\mathbf{X}$ is distributed multivariate normally:

1. Linear combinations of $\mathbf{X}$ are normally distributed

2. All subsets of $\mathbf{X}$ are multivariate normally distributed

3. A zero covariance between a pair of variables of $\mathbf{X}$ implies that the variables are independent

4. Conditional distributions of $\mathbf{X}$ are multivariate normal

Multivariate Normal Distribution in PROC IML

- To demonstrate how the MVN works, we will now investigate how the PDF provides the likelihood (height) for a given observation:
  - Here we will use the SAT data and assume the sample mean vector and covariance matrix are known to be the true:

$$\boldsymbol{\mu} = \begin{bmatrix} 499.32 \\ 498.27 \end{bmatrix}; \mathbf{S} = \begin{bmatrix} 2{,}477.34 & 3{,}123.22 \\ 3{,}132.22 & 6{,}589.71 \end{bmatrix}$$

- We will compute the likelihood value for several observations (SEE EXAMPLE SAS SYNTAX FOR HOW THIS WORKS):
  - $\boldsymbol{x}_{631,\cdot} = [590 \quad 730]; f(\boldsymbol{x}) = 0.00000087528$
  - $\boldsymbol{x}_{717,\cdot} = [340 \quad 300]; f(\boldsymbol{x}) = 0.00000037082$
  - $\boldsymbol{x} = \overline{\boldsymbol{x}} = [499.32 \quad 498.27]; f(\boldsymbol{x}) = 0.0000624$

- Note: this is the height for these observations, not the joint likelihood across all the data
  - Next time we will use PROC MIXED to find the parameters in $\boldsymbol{\mu}$ and $\boldsymbol{\Sigma}$ using maximum likelihood

Likelihoods…From SAS

```
*MULTIVARIATE NORMAL DISTRIBUTION FUNCTION CALCULATIONS;
*CONSTANTS FOR ALL CALCULATIONS:;

PI = CONSTANT('pi'); *the constant pi;
NVAR = NCOL(X); *the number of variables in X;

pi_constant = (2*PI)**(NVAR/2);
sigma_constant = DET(cov_matrix)**(1/2);
sigma_inverse = INV(cov_matrix);

*OBSERVATION #631:;
obs = X[631,];
mean_diff = t(obs)-meanvec;
exponent_term = (-1/2)*t(mean_diff)*sigma_inverse*mean_diff;
likelihood = (1/pi_constant)*(1/sigma_constant)*exp(exponent_term);
```

$$f(\mathbf{x}_p) = \frac{1}{(2\pi)^{\frac{v}{2}} |\boldsymbol{\Sigma}|^{\frac{1}{2}}} \exp\left[-\frac{\left(\mathbf{x}_p^T - \boldsymbol{\mu}\right)^T \boldsymbol{\Sigma}^{-1} \left(\mathbf{x}_p^T - \boldsymbol{\mu}\right)}{2}\right]$$

WRAPPING UP

Wrapping Up

- Matrix algebra is the language of multivariate statistics
  - Learning the basics will help you read work (both new old)
- Over the course of the rest of the semester, we will use matrix algebra frequently
  - It provides for more concise formulae
- In practice, we will use matrix algebra very little
  - But understanding how it works is the key to understanding how statistical methods work and are related

Wrapping Up

- The last two classes set the stage to discuss multivariate statistical methods that use maximum likelihood

- Matrix algebra was necessary so as to concisely talk about our distributions (which will soon be models)

- The multivariate normal distribution will be necessary to understand as it is the most commonly used distribution for estimation of multivariate models

- Next week we will get back into data analysis – but for multivariate observations…using SAS PROC MIXED
  - Each term of the MVN will be mapped onto the PROC MIXED output
